# *Stochastic?*

*Random House Unabridged Dictionary*

*sto chas tic*

*–adjective*

of or pertaining to a process involving a randomly determined sequence of observations each of which is considered as a sample of one element from a probability distribution.

In other words: Random

From the Greek: *stokhastikos* (“To Guess At”)

# *Important Distinctions*

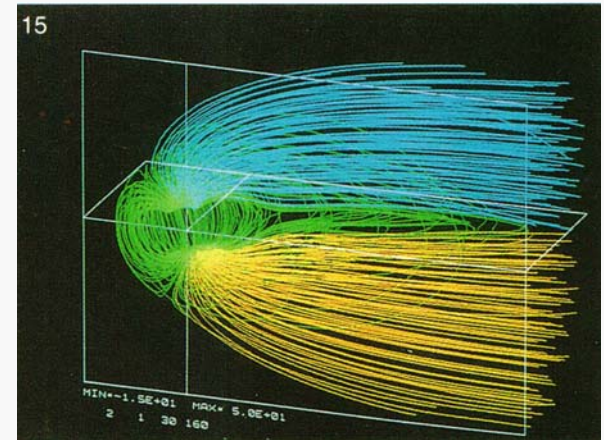

Computer Simulation

versus

Stochastic Modeling

versus

Scenario Testing

# *What is Random?*

# *What is Random?*

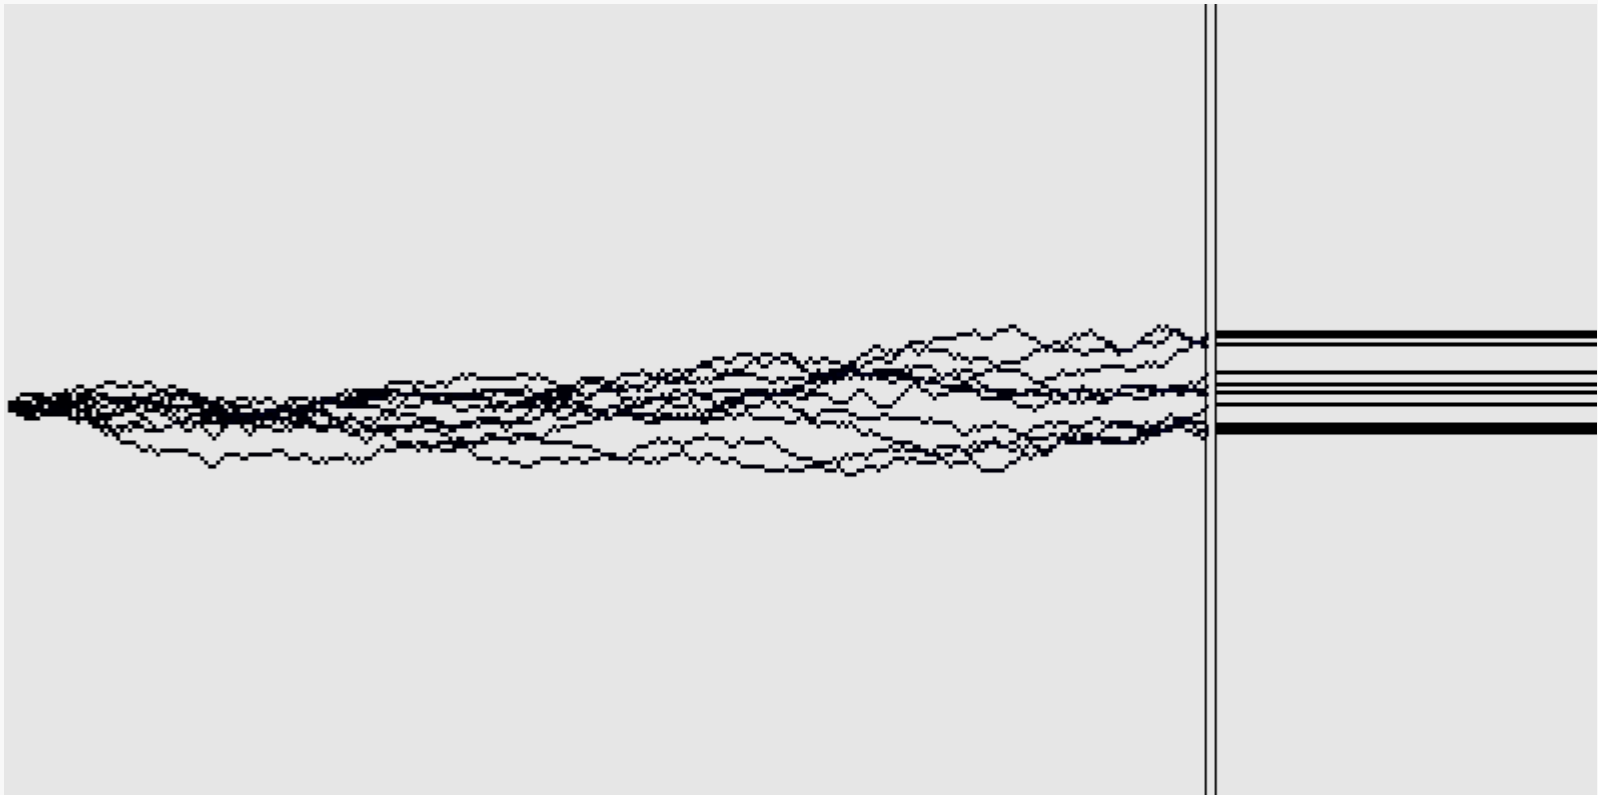

Isolated unpredictability can lead to aggregate certainty

# *Random Walk*

One walker: Equal chance of moving up or down

# *Random Walk*

10 walkers, 600 steps each

# *Random Walk*

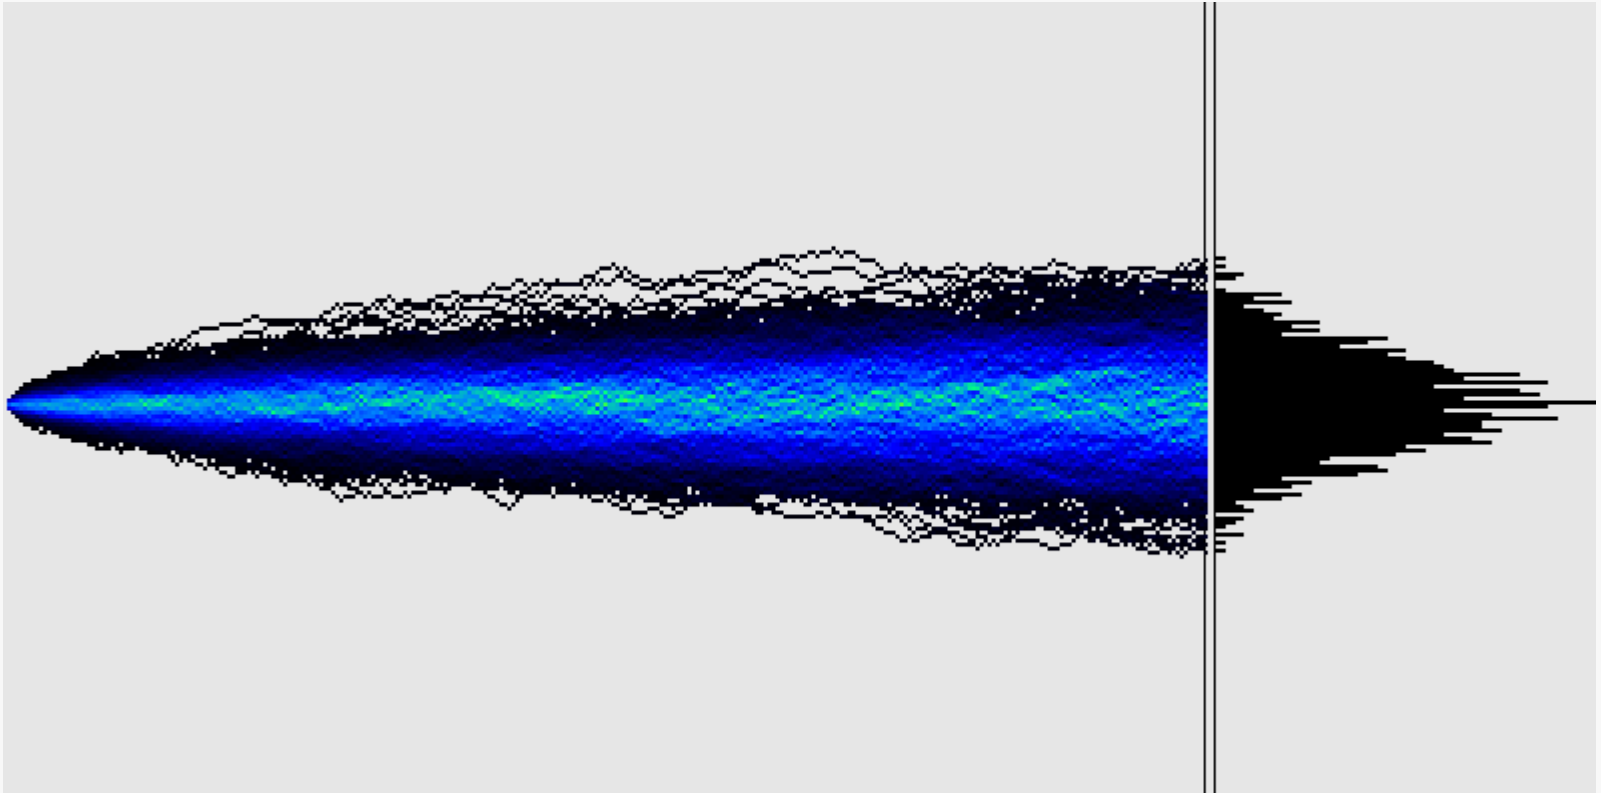

100 walkers, 600 steps each

# *Random Walk*

500 walkers, 600 steps each

# *Random Walk*

1000 walkers, 600 steps each

# *Random Walk*

5,000 walkers, 600 steps each

# *Random Walk*

Distribution approaches Normal with mean of 0 and standard deviation equal to the square root of the number of steps

# *Properties of a Normal Distribution*

3.5%  
3.0%  
2.5%  
2.0%  
0.0%

Mean = Median = Mode

Outliers are Prohibitively Rare

## Probabilities of being less than ...

Mean minus One Std Dev	15.9%	
Mean minus Two Std Dev	0.13%	
Mean minus Three Std Dev	0.0032%	
Mean minus Four Std Dev	2.87E-07	
Mean minus Five Std Dev	9.87E-10	<= One in a Billion
Mean minus Ten Std Dev	1.91E-28	<= Will never happen

75	0.3%	0.2%

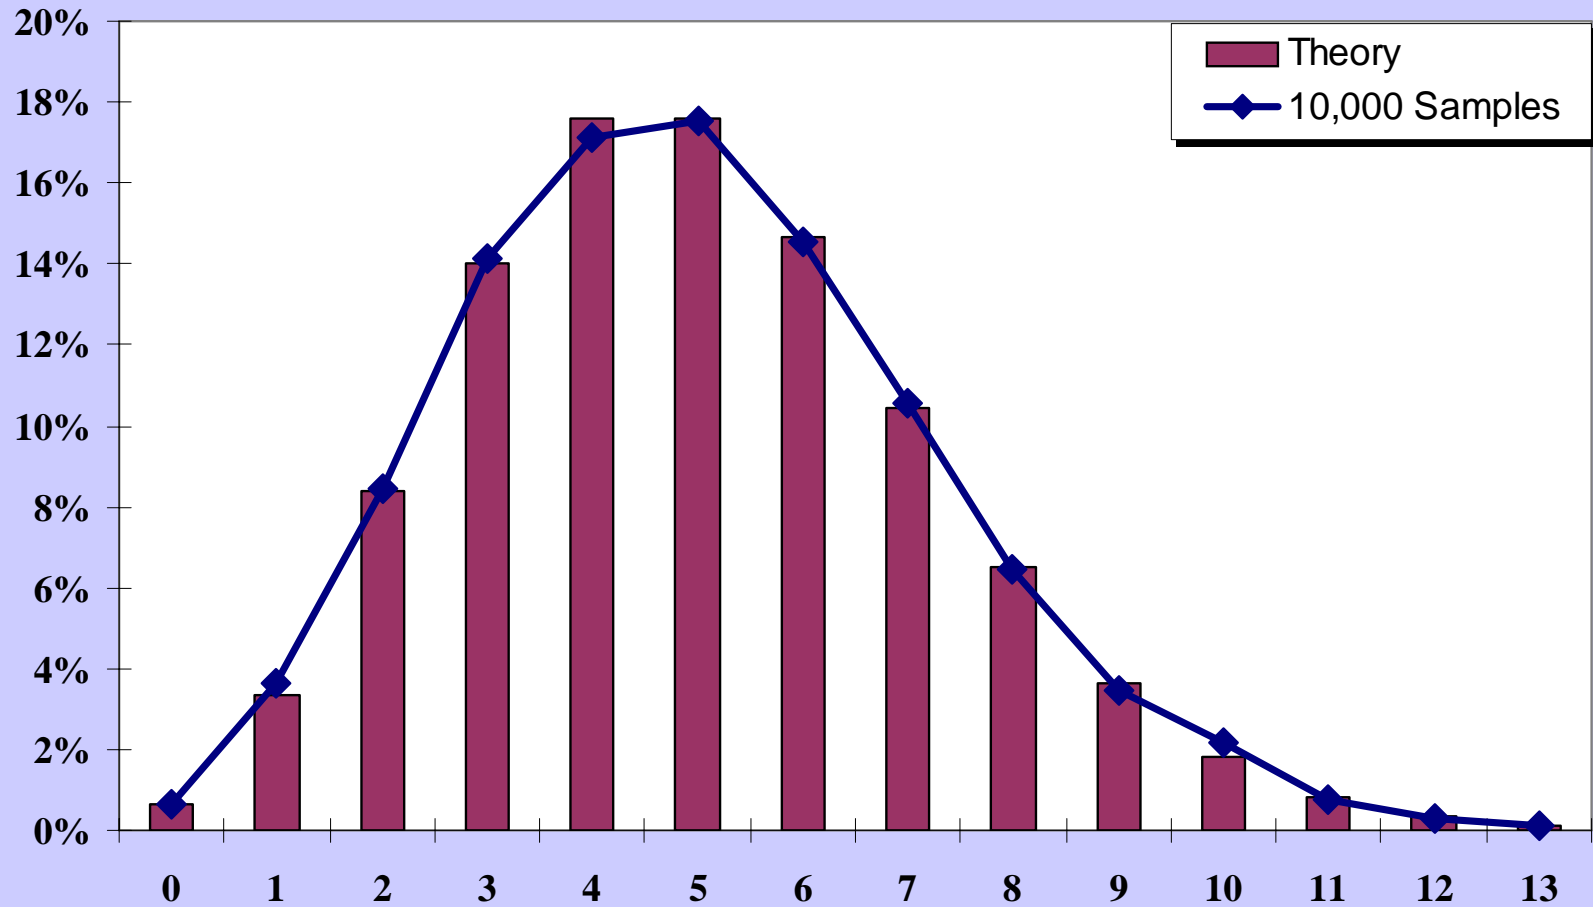

# *Incidence Simulation: 5 Expected Claims*

# *Incidence Simulation: 5 Expected Claims*

# *Incidence Simulation: 5 Expected Claims*

# *Incidence Theory*

Chance of  $X$  claims, given  $N$  lives, and Incident Rate  $P$

*Binomial Distribution*

$$P(X, N, p) = \frac{N!}{(N - X)! X!} p^X q^{N - X}$$

Mean:  $Np$

Percent Standard Deviation

Variance:  $Np(1-p)$

$$\cong \frac{1}{\sqrt{Np}}$$

Binomial Distribution approximates Normal Distribution when

$$Np(1-p) > 5, \quad \text{and} \quad (0.1 < p < 0.9 \text{ or } \min(Np) > 10)$$

# *Incidence plus Claim Size*

Case 1: 10 expected claims: all lives have the same salary

Case 2: 10 expected claims: lives have actual salaries

Spread of Salaries does produce additional variance in the loss

*If incidence and claim size are independent than the variances add.*

# *Consider Claim Duration: (Not Normal)*

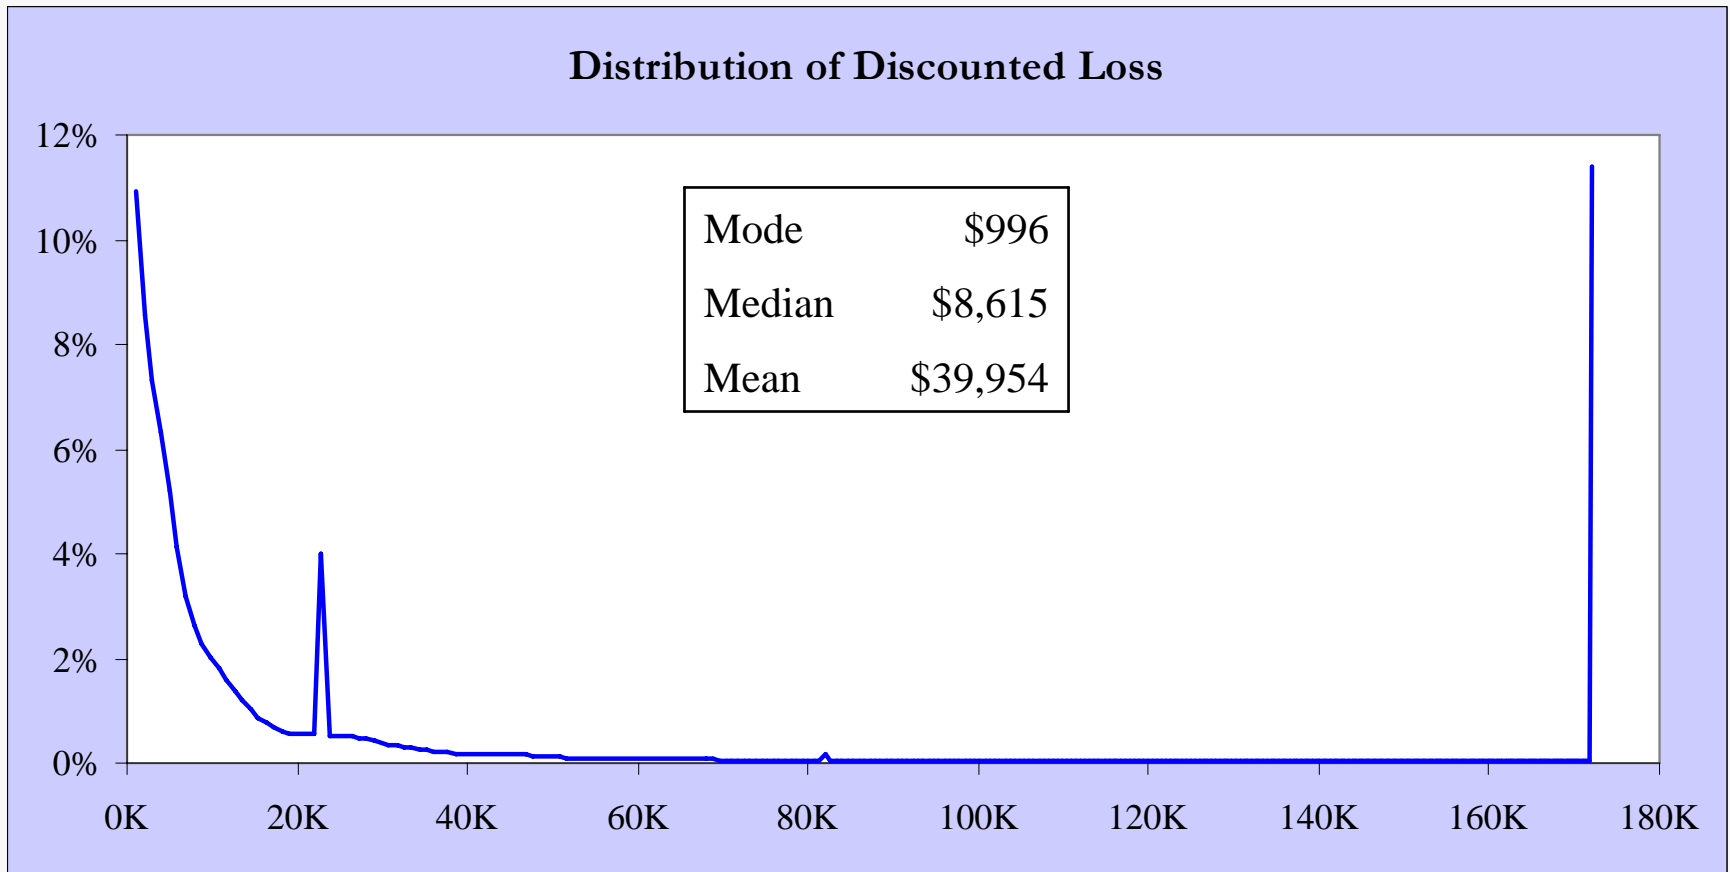

Table95a: 40 Year Old Male, 90 Day EP, \$1000 Net Benefit

# *Stochastic Simulation: Total Claim Cost*

**Distribution of Loss:**

**5 Claims**

# *Stochastic Simulation: Total Claim Cost*

Distribution of Loss:

50 Claims

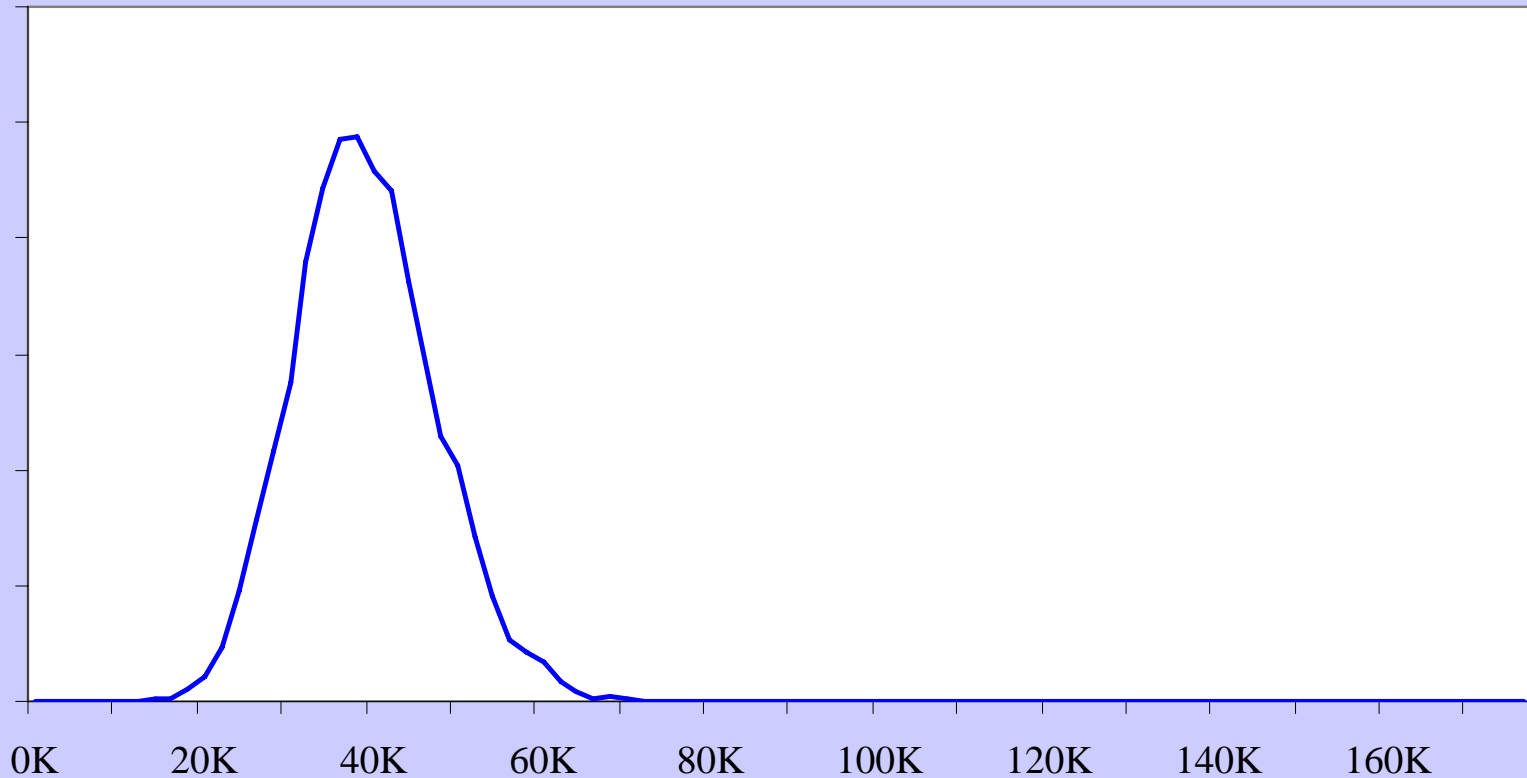

Table95a: 40 Year Old Male, 90 Day EP, \$1000 Net Benefit

# *Stochastic Simulation: Total Claim Cost*

## *Remember that Statistics Class?*

Central Limit Theorem: The sum of independent identically distributed random variables with finite variance will tend towards a normal distribution as the number of variables increase.

*\*\*\* explains the prevalence of normal distributions \*\*\**

... or...

The distribution of an average tends to be *Normal*, even when the distribution from which the average is computed is decidedly non-Normal. Furthermore, this normal distribution will have the same mean as the parent distribution, *and*, variance equal to the variance of the parent divided by the sample size.

*Standard Deviation varies as  $1/\sqrt{N}$*

# *Is everything Normal?*

Of course not: Key is average of many independent observations with similar expectations

With three different expectations, we will expect this distribution, regardless of the number of observations, but class averages will be normally distributed

## *Application to Disability Insurance*

For a large, and diverse block: Random variations produce expected distributions that are normal with standard deviation that varies as  $X / \sqrt{N}$

- $X$  depends on exposure details but varies between 1.2 and 1.5
- Simple Stochastic Simulation adds little new information

For a \$500 million dollar block this translates into expected deviation of 2.5% per quarter, or 1.25% year over year.

but ...

*...Observed variations exceed this by at least a factor of 3 to 5*

# *Stochastic Simulation in Disability Insurance*

Let's Summarize ...

1. Results can be determined analytically without use of the stochastic model
2. Results are incorrect (inconsistent with reality)

What went wrong???

Obviously there are additional sources of variance  
... but there may be something else going on.

# *Mild versus Severe Randomness*

Take a look at other Random Processes

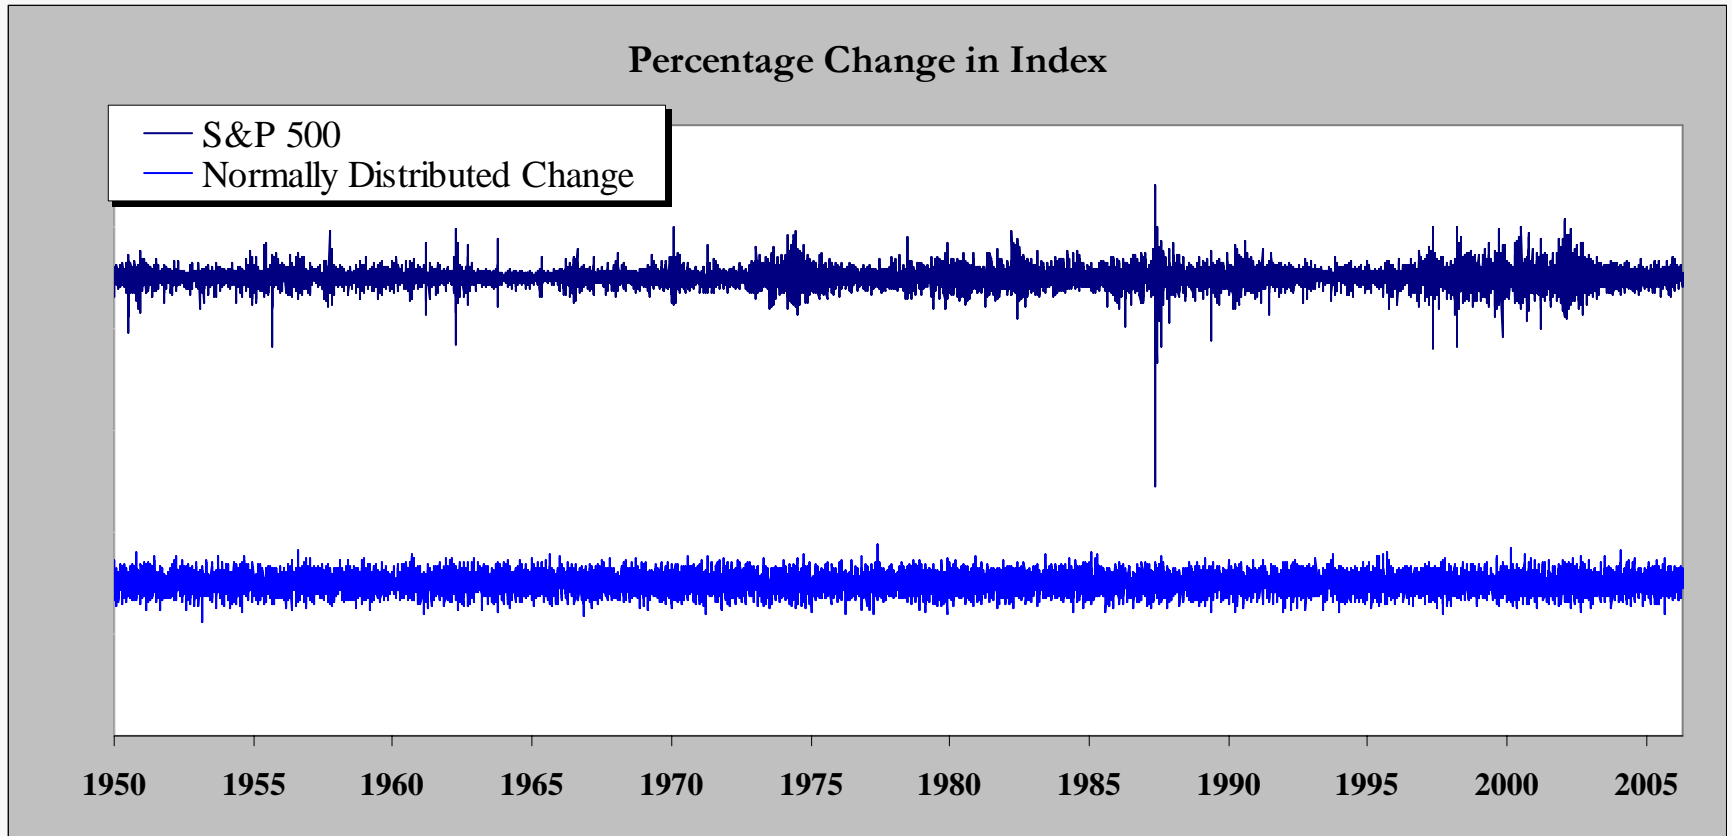

# *Mild versus Severe Randomness*

Is random walk approach appropriate?

This is the assumption underlying Black-Scholes option pricing, Capital Asset Pricing Model, etc

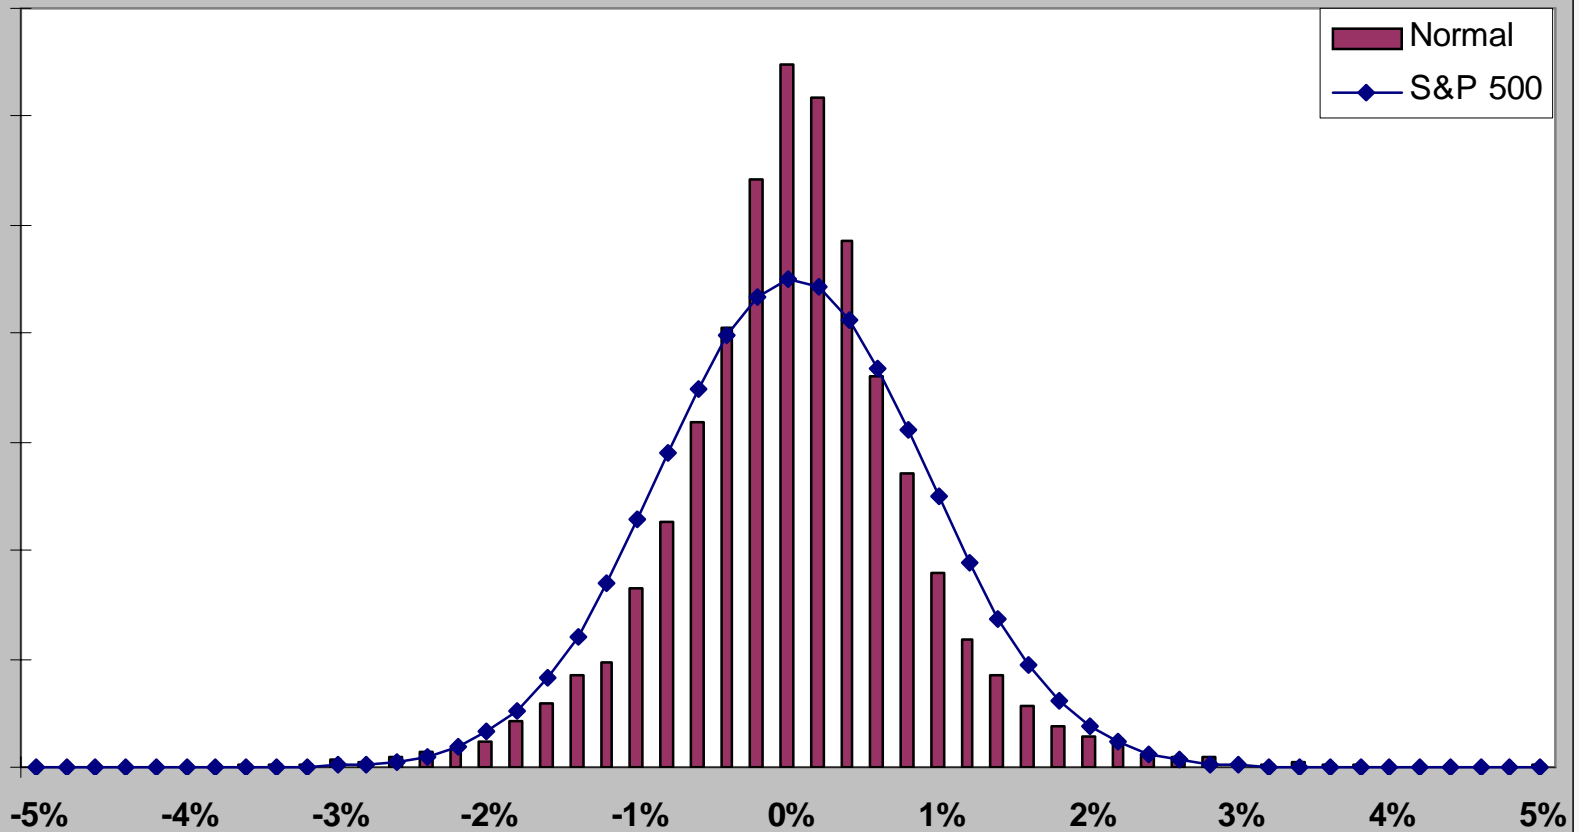

# *Mild versus Severe Randomness*

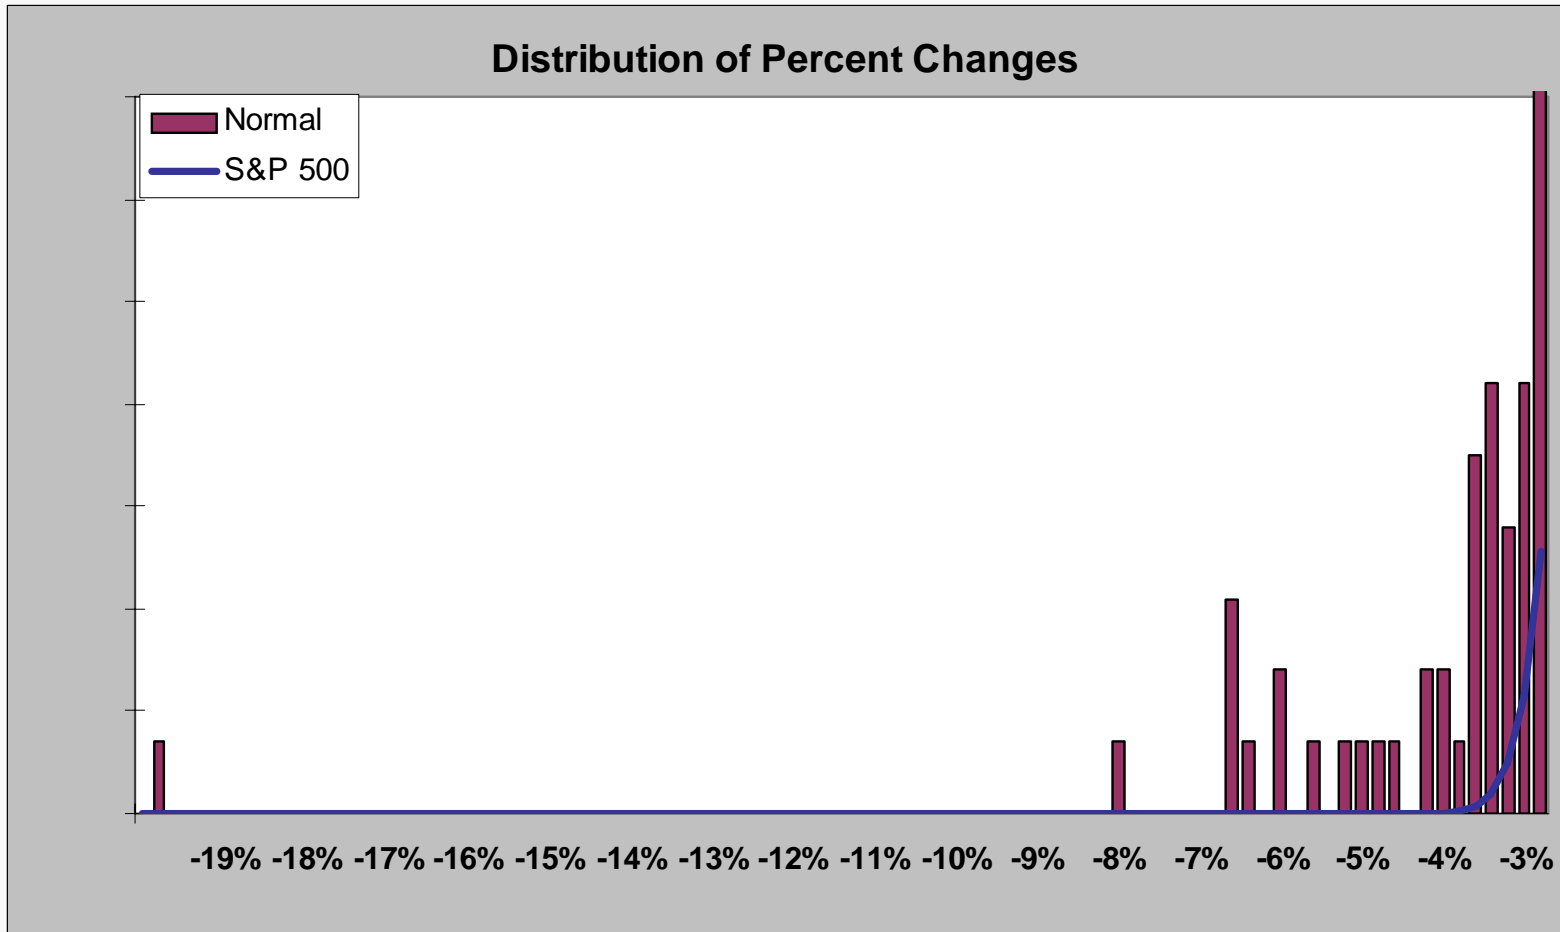

S&P Index shows higher frequency of big changes

# *Mild versus Severe Randomness*

Distribution of Percent Changes

# *Mild versus Severe Randomness*

Stochastic Modeling using Normal Randomness  
does not predict the Outliers

# *Mild versus Severe Randomness*

## S&P 500: The Biggest daily Changes

### 10 Worst Days

Date	Change	Odds	
10/20/87	-20.4%	5.31E-118	<== Will Never Happen
10/27/87	-8.3%	7.41E-21	
10/28/97	-6.9%	6.09E-15	
9/1/98	-6.8%	6.09E-15	
1/11/88	-6.8%	6.09E-15	
9/26/55	-6.6%	3.48E-14	
5/29/62	-6.2%	9.82E-13	
10/16/89	-6.1%	9.82E-13	
4/17/00	-5.8%	2.27E-11	
6/26/50	-5.4%	4.28E-10	<== 4 in 10 Billion

Stochastic Modeling using Normal Randomness  
does not predict the Outliers

# *Mild versus Severe Randomness*

## **S&P 500: The Biggest daily Changes**

### **10 Best Days**

Date	Change	Odds	
10/30/87	4.9%	6.63E-09	6 out of 1 Billion
1/4/01	5.0%	6.63E-09	
9/9/98	5.1%	6.63E-09	
10/29/97	5.1%	1.73E-09	
10/21/87	5.2%	1.73E-09	
10/10/74	5.3%	4.28E-10	
7/30/02	5.4%	4.28E-10	
7/25/02	5.7%	2.27E-11	
5/31/62	5.9%	4.84E-12	
10/22/87	9.0%	1.02E-24	<== Will Never Happen

Stochastic Modeling using Normal Randomness  
does not predict the Outliers

# *Mild versus Severe Randomness*

In real world markets, “fat tail” experience is common.

1. S&P 500
2. NASDAQ
3. Bond Prices
4. Commodity Prices
5. Currency Markets

All show more volatile extremes than simple stochastic modeling would predict... leading to underestimating the odds of catastrophic events

What about Disability Insurance ??

# *What is wrong with the Random Walk?*

Central Limit Theorem: The sum of **independent** identically distributed random variables with finite variance will tend towards a normal distribution as the number of variables increase.

Market Price changes are not independent.

Correlation across time: Feedback (Hysteresis)

Generally...

Negative Feedback = Stable, self-correcting behavior

Positive Feedback = Unstable, vicious cycles, death spiral, etc

Can produce wildly unpredictable behavior (chaotic)

# *Variability in Disability Insurance*

Does Disability Insurance have a feedback mechanism?

Experience itself may, but only minimally

Insurance company process definitely does, but tends to be self correcting.

## **External Influences**

1. Economic Cycles (global, and by region, industry, etc)
2. Underwriting Cycles (process change, reaction to sales, market dynamics)
3. Other Process Change (changes in benefits process, workloads, etc)
4. Other external factors (emergence of new disabilities, changes in work ethic or work environment, changes in Social Security practice, etc)

## *Lessons on Stochastic Modeling*

Useful as a tool for understanding dynamics, but short on predictive power

Least useful for predicting catastrophic events (where it is most needed).

Simple application *will* underestimate volatility

Very useful for gaining hands-on experience and familiarity with statistical behavior

Stochastic Modeling Paradox: Can only predict qualitative behavior, but expectations of qualitative behavior are used to decide the reasonability of the model.
